## Possibilities of High-Temperature Desulphurization and Dechlorination of a Producer Gas

*Student: Ing. Jiří Brynda*

*Supervisor: Ing. Siarhei Skoblja, Ph. D.*

*Supervising Expert: doc. Ing. Karel Svoboda, CSc.*

Producer gas contains several types of impurities, the limit of which is its further utilization. Depending on the used feedstock and type of gasifier the main impurities are dust, tar, sulphur compounds, HCl, and HF. In producer gas from biomass gasification the main impurities are tar, H<sub>2</sub>S, COS, and HCl. In order to use the producer gas in SOFC (solid oxide fuel cells) or Fischer-Tropsch synthesis the concentration of impurities has to be lower than 1 ppmv.<sup>1</sup>

For high temperature desulphurization are commonly used CaO, Fe<sub>x</sub>O<sub>y</sub>, ZnO, CuO, MnO based sorbents. In experimental studies for deep desulphurization, rare earth sorbent such as Ce<sub>2</sub>O<sub>3</sub>, CeO<sub>2</sub>, La<sub>2</sub>O<sub>3</sub> have also been investigated. For the evaluation of different sorbents equilibrium concentrations of H<sub>2</sub>S and HCl were calculated from thermodynamic data given by Barrin.<sup>2</sup> Input gas composition was 40 vol. % of H<sub>2</sub>, 10 vol. % of H<sub>2</sub>O, and 30 vol. % of CO<sub>2</sub>. At temperatures in the range of 600–800 K ZnO, Ce<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> based sorbents are able to ensure output concentrations of H<sub>2</sub>S and COS below 1 ppmv and below 0.01 ppmv, respectively. The best equilibrium concentration at 800 K can be achieved by Ce<sub>2</sub>O<sub>3</sub>. However, trivalent Ce isn't stable and in the presence of CO<sub>2</sub> or H<sub>2</sub>O undergoes oxidation to CeO<sub>2</sub> with much higher equilibrium concentration of H<sub>2</sub>S. ZnO sorbents are also problematic due to volatility of elemental zinc under reducing conditions.

Producer gas equilibrium concentrations of HCl containing 10 vol. % of H<sub>2</sub>O and 100 ppmv of HCl or 10 ppmv respectively, were calculated to predict interferences with HCl during gas desulphurization and the possibility of simultaneous desulphurization and dechlorination (de-HCl) by one of these sorbents. ZnO and Ce-based sorbents show a higher equilibrium concentration of HCl. Therefore interferences caused by HCl during desulphurization can be excluded. La<sub>2</sub>O<sub>3</sub> exerts the lowest equilibrium concentration of HCl in the producer gas and reacts in temperatures up to 900 K. It should be noted that for deep

de-HCl soda-based sorbents are needed. According to thermodynamic calculation the reaction of  $\text{Na}_2\text{CO}_3$  with  $\text{H}_2\text{S}$  should be negligible.

In the experimental part of the desulfurization and de-HCl studies,  $\text{H}_2\text{S}$  interference during dechloration was measured. Gas hourly space velocity was around  $3000 \text{ h}^{-1}$  (standard temperature and pressure). Output gas HCl concentration was about 3 ppmv which shows that it was not affected by  $\text{H}_2\text{S}$ . However a sharp decrease of sorbent capacity was observed, due to the formation of elemental sulfur from  $\text{H}_2\text{S}$  which was investigated under the condition of a model gas with dry nitrogen (without water vapor and hydrogen). The formation of elemental sulfur ( $\text{S}_x$  molecules) and its adsorption on sorbents plugs sorbent pores. Therefore the presence of hydrogen and water vapor in gas is desirable to suppress this phenomenon.

According to thermodynamic calculations  $\text{Ce}_2\text{O}_3$  exerts the highest affinity to  $\text{H}_2\text{S}$  and is capable of deep desulfurization at temperatures up to 800 K.  $\text{Ce}_2\text{O}_3$  can be stabilized by  $\text{La}_2\text{O}_3$  or MnO addition under common reduction conditions. Therefore  $\text{Ce}_2\text{O}_3$  sorbents doped by  $\text{La}_2\text{O}_3$  seem to be promising producer gas sorbents.
