The advanced applications (e.g. catalytic processes and fueling of high temperature fuel cells) of producer gas from gasification processes are extremely sensitive to inorganic and organic contaminants in the gas and on limits of cleaning processes. Among the gas contaminants, stable halogen containing compounds, HCl, HF and HBr produced in the gasification process should be considered as clear candidates for deep removal. Producer gas cleaning for attaining hydrogen-halides concentrations approx. below 1 ppm<sub>v</sub> requires either application of low temperature wet absorption processes or, particularly for fueling of high temperature fuel cells (SOFC), deployment of medium and high temperature (600 – 1200 K) cleaning methods with solid sorbents. Our study is focused on thermodynamic analyses and minimization of Gibbs energy for gas de-halogenation (removal of HCl, HF and HBr) by selected solid sorbents ( $\text{Na}_2\text{CO}_3$ ,  $\text{NaAlO}_2$ ,  $\text{CaO}/\text{CaCO}_3$ ,  $\text{BaO}/\text{BaCO}_3$ , and mixtures containing  $\text{CaO-BaO}/\text{BaCO}_3$ ). The cheap  $\text{Na}_2\text{CO}_3$  and  $\text{NaAlO}_2$  based sorbents are suitable for deep removal of HCl and particularly HBr at temperatures below 800 K, but they are less suitable for HF removal. For attaining low HF equilibrium concentrations rather the  $\text{CaO}/\text{CaCO}_3$  based sorbents are the best choice. The promising  $\text{BaO}/\text{BaCO}_3$  based sorbents and mixed  $\text{CaO-BaO}/\text{BaCO}_3$  sorbents for removal of HCl, HBr and HF (or even their mixtures with  $\text{H}_2\text{S}$ ) are dependent on appropriate solid solution form stabilizing BaO for its sorption applications, because BaO has significantly more favorable equilibria than  $\text{BaCO}_3$  with all studied hydrogen-halides. Unfortunately stabilization of BaO in mixtures with CaO and similar compounds requires temperatures over 1150 K – 1200 K.
