# An Improvement of the Bauer-Skeel Bounds

Jiří Rohn<sup>1</sup>

Technical report No. V-1065

22.02.2010

Abstract:

It is shown that the Hansen-Bliek-Rohn bounds are never worse, and "almost always" better, than the classical Bauer-Skeel bounds. Formulae for overestimation of the Hansen-Bliek-Rohn bounds are given.

Keywords: Bauer-Skeel bounds, Hansen-Bliek-Rohn bounds, comparison, overestimation.

 $<sup>^1 \</sup>rm Supported$  by the Czech Republic Grant Agency under grant 201/01/0343, and by the Institutional Research Plan AV0Z10300504.

### 1 Introduction

This is transcription of slides of a talk I delivered at the Bergische Universität Wuppertal, Germany on Dec. 9, 2003. It has never been made a regular paper. So after six years, I decided to make it at least a report written in a terse "slide-like" style. Theorems 3 through 6 are new.

#### 2 Notations

understood componentwise. Especially,

 $|A - B| \le C$ 

is equivalent to

$$B - C \le A \le B + C.$$

### 3 The problem

Given a fixed system

 $A_c x_c = b_c$ 

with  $A_c$  nonsingular, and a perturbed system

$$Ax = b$$

such that

$$\begin{aligned} |A - A_c| &\leq \Delta, \\ |b - b_c| &\leq \delta, \end{aligned}$$

estimate

 $\ldots \leq x \leq \ldots$ 

in terms of  $x_c$ ,  $A_c^{-1}$ ,  $\Delta$  and  $\delta$ .

#### 4 Assumption

We shall assume throughout that the data satisfy

$$\varrho(|A_c^{-1}|\Delta) < 1.$$

Under this *spectral condition* we have

$$M := (I - |A_c^{-1}|\Delta)^{-1} = \sum_{j=0}^{\infty} (|A_c^{-1}|\Delta)^j \ge I \ge 0.$$

In particular,

$$M_{ii} \ge 1$$

for each i (a property which will turn out extremely important).

## 5 The Bauer-Skeel bounds

Theorem 1. (Bauer 1966, Skeel 1979) If

 $\varrho(|A_c^{-1}|\Delta) < 1,$ 

then for each A, b such that  $|A - A_c| \leq \Delta$  and  $|b - b_c| \leq \delta$ , A is nonsingular and the solution of

$$Ax = b$$

satisfies

$$-x^* + x_c + |x_c| \le x \le x^* + x_c - |x_c|$$

where

$$M = (I - |A_c^{-1}|\Delta)^{-1},$$
  
$$x^* = M(|x_c| + |A_c^{-1}|\delta).$$

Note. Usually presented as  $|x - x_c| \le x^* - |x_c|$ , with  $\delta = 0$  or in normwise setting. Two inversions needed.

#### 6 Proof

We have

$$A_c^{-1}A = I - A_c^{-1}(A_c - A),$$

where

$$\varrho(A_c^{-1}(A_c - A)) \le \varrho(|A_c^{-1}(A_c - A)|) \le \varrho(|A_c^{-1}|\Delta) < 1,$$

hence  $A_c^{-1}A$  is nonsingular and thus also A. If Ax = b, then

$$|x - x_c| = |A_c^{-1}A_c(x - x_c)| \\ \leq |A_c^{-1}| \cdot |(A_c - A)x + (b - b_c)| \\ \leq |A_c^{-1}|(\Delta |x| + \delta).$$

[Attention: This is the bifurcation point of the two proofs.]

$$|x - x_c| \leq |A_c^{-1}|(\Delta |x| + \delta) = |A_c^{-1}|(\Delta |x - x_c + x_c| + \delta)$$
  
$$\leq |A_c^{-1}|\Delta |x - x_c| + |A_c^{-1}|(\Delta |x_c| + \delta),$$

hence

$$(I - |A_c^{-1}|\Delta)|x - x_c| \le |A_c^{-1}|(\Delta|x_c| + \delta).$$

Premultiplying by  $M = (I - |A_c^{-1}|\Delta)^{-1} \ge 0$ :

$$|x - x_c| \leq M |A_c^{-1}| (\Delta |x_c| + \delta) = (M - I) |x_c| + M |A_c^{-1}| \delta = x^* - |x_c|$$

and equivalently

$$-x^* + x_c + |x_c| \le x \le x^* + x_c - |x_c|.$$

## 7 The HBR bounds

Theorem 2. (Hansen 1992, Bliek 1992, R. 1993) Under the same assumption

$$\varrho(|A_c^{-1}|\Delta) < 1$$

we have

 $\min\{x, Tx\} \le x \le \max\{\tilde{x}, T\tilde{x}\},\$ 

where

$$M = (I - |A_c^{-1}|\Delta)^{-1},$$
  

$$D = \text{diag}(M_{11}, \dots, M_{nn}),$$
  

$$T = (2D - I)^{-1},$$
  

$$x^* = M(|x_c| + |A_c^{-1}|\delta),$$
  

$$x = -x^* + D(x_c + |x_c|),$$
  

$$\tilde{x} = x^* + D(x_c - |x_c|).$$

#### 8 Proof

As in the proof of the Bauer-Skeel bounds we proceed up to the "bifurcation point"

$$|x - x_c| \le |A_c^{-1}|(\Delta |x| + \delta),$$

but then we continue in another way: we have on one hand

$$x - x_c \le |x - x_c| \le |A_c^{-1}|(\Delta |x| + \delta)$$
(8.1)

and on the other hand

$$|x| - |x_c| \le |x - x_c| \le |A_c^{-1}| (\Delta |x| + \delta).$$
(8.2)

For *i* fixed, take the *i*th inequality from (8.1) and for  $j \neq i$  from (8.2):

$$x_{i} \leq (x_{c})_{i} + (|A_{c}^{-1}|(\Delta|x| + \delta))_{i}$$
$$x_{j}| \leq |x_{c}|_{j} + (|A_{c}^{-1}|(\Delta|x| + \delta))_{j}, \quad j \neq i$$

 $|x_j| \le |x_c|_j + (|A_c^{-1}|(\Delta|x| + \delta))_j, \quad j \ne i.$ Since  $x_i = |x_i| + (x_i - |x_i|)$  and the same holds for  $(x_c)_i$ , we can put them together as

$$|x| + (x_i - |x_i|)e_i \le |x_c| + ((x_c)_i - |x_c|_i)e_i + |A_c^{-1}|(\Delta |x| + \delta),$$

which implies

$$(I - |A_c^{-1}|\Delta)|x| + (x_i - |x_i|)e_i \le |x_c| + ((x_c)_i - |x_c|_i)e_i + |A_c^{-1}|\delta.$$

Again premultiplying by  $M = (I - |A_c^{-1}|\Delta)^{-1} \ge 0$ :

$$|x| + (x_i - |x_i|)Me_i \le x^* + ((x_c)_i - |x_c|_i)Me_i$$

and taking the ith inequality we get

$$|x_i| + (x_i - |x_i|)M_{ii} \le x_i^* + ((x_c)_i - |x_c|_i)M_{ii} = \tilde{x}_i$$

an inequality containing  $x_i$  only. If  $x_i \ge 0$ , then this inequality becomes

$$x_i \leq \tilde{x}_i,$$

and if  $x_i < 0$ , then it turns into

$$x_i \le \tilde{x}_i / (2M_{ii} - 1) = T_{ii} \tilde{x}_i,$$

in both cases

$$x_i \le \max\{\tilde{x}_i, T_{ii}\tilde{x}_i\}.$$

Since i was arbitrary, we conclude that

$$x \le \max\{\tilde{x}, T\tilde{x}\},\$$

which is the upper bound. Similarly for the lower one.

#### 9 Comparison: preliminaries

For comparison, denote the Bauer-Skeel bounds by

 $\underline{x} \leq x \leq \overline{x}$ 

and the HBR bounds by

 $\underline{\underline{x}} \le x \le \overline{\overline{x}},$ 

i.e.

$$\underline{x} = -x^* + x_c + |x_c|,$$
  

$$\overline{x} = x^* + x_c - |x_c|,$$
  

$$\underline{x} = \min\{x, Tx\},$$
  

$$\overline{\overline{x}} = \max\{\tilde{x}, T\tilde{x}\}.$$

It turns out that crucial for the comparison is the fact that

 $M_{ii} \geq 1$  for each *i*.

#### 10 Main result

**Theorem 3.** Under the common assumption  $\varrho(|A_c^{-1}|\Delta) < 1$ , for each *i* we have

$$\overline{x}_{i} - \overline{\overline{x}}_{i} \ge \min\left\{ (M_{ii} - 1)(|x_{c}|_{i} - (x_{c})_{i}), \frac{2(M_{ii} - 1)}{2M_{ii} - 1}(x_{i}^{*} - |x_{c}|_{i}) \right\} \ge 0,$$
  
$$\underline{x}_{i} - \underline{x}_{i} \ge \min\left\{ (M_{ii} - 1)(|x_{c}|_{i} + (x_{c})_{i}), \frac{2(M_{ii} - 1)}{2M_{ii} - 1}(x_{i}^{*} - |x_{c}|_{i}) \right\} \ge 0.$$

In particular,

$$\underline{x} \le \underline{x} \le \overline{\overline{x}} \le \overline{x}$$

*i.e.* the HBR bounds are *never worse* than the Bauer-Skeel bounds.

**Remark.** Nonnegativity follows from the facts that  $M \ge I$  and  $x^* = M(|x_c| + |A_c^{-1}|\delta) \ge |x_c|$ .

#### 11 Refinement

**Theorem 4.** Let the spectral condition hold. Then for each *i* such that  $M_{ii} > 1$  and  $(x_c)_i \neq 0$  we have

$$(\overline{x}_i - \underline{x}_i) - (\overline{\overline{x}}_i - \underline{x}_i) \ge \frac{2(M_{ii} - 1)^2}{2M_{ii} - 1} |x_c|_i > 0,$$

hence

 $\overline{\overline{x}}_i - \underline{\underline{x}}_i < \overline{x}_i - \underline{\underline{x}}_i,$ 

i.e., the ith HBR bound is better than the Bauer-Skeel bound.

**Remark.** Recall that  $M = (I - |A_c^{-1}|\Delta)^{-1} = \sum_{j=0}^{\infty} (|A_c^{-1}|\Delta)^j \ge I$ . Hence  $M_{ii} > 1$  e.g. if  $(|A_c^{-1}|\Delta)_{ii} > 0$ .

## 12 Partial conclusion

We can conclude that the HBR bounds are "almost always" better than the Bauer-Skeel bounds. Still, how good are the HBR bounds themselves?

## 13 Exact bounds

For each i define

$$x_i^e = \min\{x_i; Ax = b, |A - A_c| \le \Delta, |b - b_c| \le \delta\}, x_i^E = \max\{x_i; Ax = b, |A - A_c| \le \Delta, |b - b_c| \le \delta\}.$$

Obviously,  $x^e$  and  $x^E$  are exact componentwise bounds, so that they satisfy

$$\underline{\underline{x}} \le x^e \le x^E \le \overline{\overline{x}}$$

 $(x^e, x^E \text{ are NP-hard to compute})$ . Now, what is the amount of overestimation?

### 14 Overestimation of the HBR bounds

**Theorem 5. (2000, not yet published)** Let the spectral condition hold. Then for each  $i \in \{1, ..., n\}$  we have

$$\underline{\underline{x}}_{i} \leq x_{i}^{e} \leq \underline{\underline{x}}_{i} + \underline{d}_{i},$$

$$\overline{\overline{x}}_{i} - \overline{d}_{i} \leq x_{i}^{E} \leq \overline{\overline{x}}_{i},$$

where

$$\begin{split} \underline{d}_i &= (M | (\operatorname{diag}(\underline{z}) A_c^{-1} \operatorname{diag}(\underline{z}) - |A_c^{-1}|) (\underline{\xi}_i \Delta M e_i + \Delta x^* + \delta) |)_i, \\ \overline{d}_i &= (M | (\operatorname{diag}(\overline{z}) A_c^{-1} \operatorname{diag}(\overline{z}) - |A_c^{-1}|) (\overline{\xi}_i \Delta M e_i + \Delta x^* + \delta) |)_i, \\ \underline{\xi}_i &= (|\underline{x}| + \underline{x} - x_c - |x_c|)_i, \\ \overline{\xi}_i &= (|\overline{x}| - \overline{x} + x_c - |x_c|)_i \end{split}$$

and  $\underline{z}, \overline{z}$  are given by

$$\underline{z}_j = \begin{cases} \operatorname{sgn}(x_c)_j & \text{if } j \neq i, \\ -1 & \text{if } j = i, \end{cases}, \quad \overline{z}_j = \begin{cases} \operatorname{sgn}(x_c)_j & \text{if } j \neq i, \\ 1 & \text{if } j = i \end{cases}, \quad (j = 1, \dots, n).$$

## 15 Example (J. Albrecht 1961)

Here  $A_c x = b_c$  reads

$$4.33x_1 - 1.12x_2 - 1.08x_3 + 1.14x_4 = 3.52$$
  
$$-1.12x_1 + 4.33x_2 + 0.24x_3 - 1.22x_4 = 1.57$$
  
$$-1.08x_1 + 0.24x_2 + 7.21x_3 - 3.22x_4 = 0.54$$
  
$$1.14x_1 - 1.22x_2 - 3.22x_3 + 5.43x_4 = -1.09$$

and

$$\Delta_{ij} = \delta_i = 0.005$$

for each i, j,

$$\varrho(|A_c^{-1}|\Delta) = 0.008.$$

#### 16 Results

(rounded to four decimal digits)  

$$[\underline{x}, \underline{x} + \underline{d}] = \begin{pmatrix} [1.0408, 1.0441] \\ [0.5567, 0.5593] \\ [0.1056, 0.1072] \\ [-0.2352, -0.2299] \end{pmatrix}, \quad [\overline{x} - \overline{d}, \overline{x}] = \begin{pmatrix} [1.0517, 1.0517] \\ [0.5670, 0.5689] \\ [0.1129, 0.1164] \\ [-0.2218, -0.2210] \end{pmatrix}.$$

## 17 Unsatisfactory result (1997)

Theorem 5 applied to the system

$$\begin{pmatrix} \varepsilon^2 & [-\varepsilon,\varepsilon] & [-\varepsilon,\varepsilon] & [-\varepsilon,\varepsilon] \\ 0 & 1.1 & 1 & 1 \\ 0 & 1 & 1.1 & 1 \\ 0 & 1 & 1 & 1.1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = \begin{pmatrix} 0 \\ [-\varepsilon,\varepsilon] \\ [-\varepsilon,\varepsilon] \\ [-\varepsilon,\varepsilon] \end{pmatrix}$$

works for each  $\varepsilon > 0$  (since  $\varrho(|A_c^{-1}|\Delta) = 0$ ) and yields independently of  $\varepsilon$ 

$$[\overline{\overline{x}}_1 - \overline{d}_1, \overline{\overline{x}}_1] = \left[\frac{30}{31}, \frac{1230}{31}\right] = [0.97, 39.68]$$

whereas  $x_1^E = \frac{830}{31} = 26.77$ , i.e.,  $\frac{\overline{x}_1 - x_1^E}{x_1^E} = \frac{40}{83} = 0.48$  (rounded to two decimal digits).

## 18 Zero overestimation cases

Theorem 6. Let the spectral condition hold. Then we have:

- (i)  $x^e = \underline{x}, x^E = \overline{\overline{x}}$  if  $A_c$  is a diagonal matrix with positive diagonal entries,
- (ii)  $x^e = \underline{x}$  if  $A_c^{-1} \ge 0$  and  $A_c^{-1}b_c \le 0$ ,
- (iii)  $x^E = \overline{\overline{x}} \text{ if } A_c^{-1} \ge 0 \text{ and } A_c^{-1}b_c \ge 0.$

## 19 Conclusions

- both the Bauer-Skeel bounds and the HBR bounds require solving  $A_c x = b_c$  and computing  $A_c^{-1}$  and  $(I |A_c^{-1}|\Delta)^{-1}$ ,
- the HBR bounds are never worse, and "almost always" better, than the Bauer-Skeel bounds,
- overestimation of the HBR bounds can be computed at almost no additional cost.
