#### Abstract

: We describe a general method for enclosing the solution set of a system of interval linear equations. We present a general theorem and an algorithm in a MATLAB-style code. The result is called a "method", not an "algorithm", because it involves solving absolute value matrix inequalities; the way how to solve these inequalities will be explained elsewhere.

Keywords:
Interval linear equations, solution set, enclosure, absolute value inequality.

[^0]
## 1 Introduction

In this report we describe a general method for enclosing the solution set of a system of interval linear equations. We present a general theorem (Theorem 3) and an algorithm in a MATLAB-style code (Fig. 5.1). We call the result a "method", not an "algorithm", because it involves solving absolute value matrix inequalities whose solution is not specified; we plan to elaborate on this issue in a forthcoming paper.

## 2 Notations

We use the following notations. Matrix inequalities, as $A \leq B$ or $A<B$, are understood componentwise. The absolute value of a matrix $A=\left(a_{i j}\right)$ is defined by $|A|=\left(\left|a_{i j}\right|\right)$. The same notations also apply to vectors that are considered onecolumn matrices. $I$ is the unit matrix, $e_{j}$ is the $j$ th column of $I$, and $e=(1, \ldots, 1)^{T}$ is the vector of all ones. $Y_{n}=\{y| | y \mid=e\}$ is the set of all $\pm 1$-vectors in $\mathbb{R}^{n}$, so that its cardinality is $2^{n}$. Vectors $y, z \in Y_{n}$ are called adjacent if they differ in exactly one entry. Obviously, $y, z \in Y_{n}$ are adjacent if and only if $y=z-2 z_{j} e_{j}$ for some $j$. For each $x \in \mathbb{R}^{n}$ we define its sign vector $\operatorname{sgn}(x)$ by

$$
(\operatorname{sgn}(x))_{i}=\left\{\begin{aligned}
1 & \text { if } x_{i} \geq 0, \\
-1 & \text { if } x_{i}<0
\end{aligned} \quad(i=1, \ldots, n)\right.
$$

so that $\operatorname{sgn}(x) \in Y_{n}$. For each $z \in \mathbb{R}^{n}$ we denote

$$
T_{z}=\operatorname{diag}\left(z_{1}, \ldots, z_{n}\right)=\left(\begin{array}{cccc}
z_{1} & 0 & \ldots & 0 \\
0 & z_{2} & \ldots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \ldots & z_{n}
\end{array}\right)
$$

and $\mathbb{R}_{z}^{n}=\left\{x \mid T_{z} x \geq 0\right\}$ is the orthant prescribed by the $\pm 1$-vector $z \in Y_{n}$.

## 3 The problem

Given an $n \times n$ interval matrix $\mathbf{A}=\left[A_{c}-\Delta, A_{c}+\Delta\right]$ and an interval $n$-vector $\mathbf{b}=$ [ $b_{c}-\delta, b_{c}+\delta$ ], the solution set of the system of interval linear equations $\mathbf{A} x=\mathbf{b}$ is defined as

$$
\mathbf{X}(\mathbf{A}, \mathbf{b})=\{x \mid A x=b \text { for some } A \in \mathbf{A}, b \in \mathbf{b}\} .
$$

The Oettli-Prager theorem [4] asserts that the solution set is described by

$$
\mathbf{X}(\mathbf{A}, \mathbf{b})=\left\{x| | A_{c} x-b_{c}|\leq \Delta| x \mid+\delta\right\} .
$$

If $\mathbf{A}$ is regular, then $\mathbf{X}(\mathbf{A}, \mathbf{b})$ is compact and connected (Beeck [1]); if $\mathbf{A}$ is singular, then each component of $\mathbf{X}(\mathbf{A}, \mathbf{b})$ is unbounded (Jansson [3]). The solution set is
generally of a complicated nonconvex structure. In practical computations, therefore, we look for an enclosure of it, i.e., for an interval vector $\mathbf{x}$ satisfying

$$
\mathbf{X}(\mathbf{A}, \mathbf{b}) \subseteq \mathbf{x}
$$

The present text is dedicated to the problem of finding such an $\mathbf{x}$ under general circumstances when regularity/singularity of $\mathbf{A}$ is not known in advance (and is verified on the way). The text owes much to Christian Jansson's ideas in [3].

## 4 The results

The core of our method consists in specifying a subset $Z$ of $Y_{n}$ such that

$$
\mathbf{X}(\mathbf{A}, \mathbf{b}) \subseteq \bigcup_{z \in Z} \mathbb{R}_{z}^{n}
$$

In the first theorem such a set $Z$ is described recursively ((a), (c) below) in terms of the solution set only.

Theorem 1 Let $\mathbf{A}$ be an $n \times n$ interval matrix, $\mathbf{b}$ an interval $n$-vector, and let $Z$ be a subset of $Y_{n}$ having the following properties:
(a) $\operatorname{sgn}\left(x_{0}\right) \in Z$ for some $x_{0} \in \mathbf{X}(\mathbf{A}, \mathbf{b})$,
(b) $\mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n}$ is bounded for each $z \in Z$,
(c) if $z, y$ are adjacent, $z \in Z, y \in Y_{n}$, and $\mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \cap \mathbb{R}_{y}^{n} \neq \emptyset$, then $y \in Z$.

Then $\mathbf{A}$ is regular and

$$
\begin{equation*}
\mathbf{X}(\mathbf{A}, \mathbf{b}) \subseteq \bigcup_{z \in Z} \mathbb{R}_{z}^{n} \tag{4.1}
\end{equation*}
$$

holds.
Proof. For brevity, denote $X=\mathbf{X}(\mathbf{A}, \mathbf{b})$. Let $X_{0}$ be the component of $X$ (i.e. a nonempty connected subset of $X$ maximal with respect to inclusion) containing $x_{0}$. We shall prove that

$$
\begin{equation*}
X_{0} \subseteq \bigcup_{z \in Z} \mathbb{R}_{z}^{n} \tag{4.2}
\end{equation*}
$$

holds. Assume to the contrary that it is not so, so that there exists an $x_{1} \in X_{0}$ such that

$$
x_{1} \notin \bigcup_{z \in Z} \mathbb{R}_{z}^{n}
$$

Since $X_{0}$ is connected, there exists a continuous mapping $\varphi:[0,1] \rightarrow X_{0}$ with $\varphi(0)=$ $x_{0}$ and $\varphi(1)=x_{1}$. Let

$$
\tau=\sup \left\{t \mid \varphi(t) \in \bigcup_{z \in Z} \mathbb{R}_{z}^{n}\right\}
$$

and put $x^{*}=\varphi(\tau)$. Then $x^{*} \in \bigcup_{z \in Z} \mathbb{R}_{z}^{n}$ because $\varphi$ is continuous and $\bigcup_{z \in Z} \mathbb{R}_{z}^{n}$ is closed, say $x^{*} \in \mathbb{R}_{z^{\prime}}^{n}, z^{\prime} \in Z$, hence $x^{*} \neq x_{1}$ and $\tau<1$. Put $\varepsilon=1-\tau$ and consider the sequence

$$
\{\varphi(\tau+\varepsilon / j)\}_{j=1}^{\infty}
$$

Since

$$
\varphi(\tau+\varepsilon / j) \in \bigcup_{z \notin Z} \mathbb{R}_{z}^{n}
$$

for each $j$ and since the set $\left\{z \in Y_{n} \mid z \notin Z\right\}$ is finite, there exists a $z^{\prime \prime} \notin Z$ such that $\varphi(\tau+\varepsilon / j) \in \mathbb{R}_{z^{\prime \prime}}^{n}$ for infinitely many $j$. Taking the limit along this subsequence, we get that $x^{*} \in \mathbb{R}_{z^{\prime \prime}}^{n}$ because $\mathbb{R}_{z^{\prime \prime}}^{n}$ is closed. Thus we have that

$$
x^{*} \in \mathbb{R}_{z^{\prime}}^{n} \cap \mathbb{R}_{z^{\prime \prime}}^{n}
$$

where $z^{\prime} \in Z$ and $z^{\prime \prime} \notin Z$, so that $z^{\prime} \neq z^{\prime \prime}$. Put

$$
I=\left\{i \mid z_{i}^{\prime} \neq z_{i}^{\prime \prime}\right\}=\left\{i_{1}, \ldots, i_{m}\right\}
$$

then

$$
x_{i}^{*}=0
$$

for each $i \in I$, and define vectors $z^{0}, z^{1}, \ldots, z^{m} \in Y_{n}$ by induction as follows:

$$
z^{0}=z^{\prime}
$$

and

$$
z^{j}:=z^{j-1}, z_{i_{j}}^{j}:=-z_{i_{j}}^{j}
$$

for $j=1, \ldots, m$. Then $z^{0} \in Z$ and by induction for each $j=1, \ldots, m, z^{j-1}$ and $z^{j}$ are adjacent, $z^{j-1} \in Z$ and $x^{*} \in \mathbb{R}_{z^{j-1}}^{n} \cap \mathbb{R}_{z^{j}}^{n}, x^{*} \in X_{0} \subseteq X$, hence $z^{j} \in Z$ by assumption (c). Thus, by induction, $z^{j} \in Z$ for each $j=0, \ldots, m$. In particular, $z^{\prime \prime}=z^{m} \in Z$, which contradicts the previously established fact that $z^{\prime \prime} \notin Z$. This contradiction finally proves that (4.2) holds.

Now, (4.2) implies that

$$
X_{0} \subseteq \bigcup_{z \in Z}\left(X_{0} \cap \mathbb{R}_{z}^{n}\right) \subseteq \bigcup_{z \in Z}\left(X \cap \mathbb{R}_{z}^{n}\right)
$$

hence the component $X_{0}$ is bounded by assumption (b). If $\mathbf{A}$ were singular, then, by Jansson's result in [3] each component of $X$ would be unbounded. Since $X_{0}$ is bounded, this implies that $\mathbf{A}$ is regular and therefore $X$ is connected (Beeck [1]); this means that $X_{0}=X$, and (4.2) implies (4.1).

In the second theorem we further assume existence of an enclosure of each nonempty set $\mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n}, z \in Z$ (without specifying how it should be found).

Theorem 2 Let $\mathbf{A}$ be an $n \times n$ interval matrix, $\mathbf{b}$ an interval $n$-vector, and let $Z$ be a subset of $Y_{n}$ having the following properties:
( $\left.a^{\prime}\right) \operatorname{sgn}\left(x_{0}\right) \in Z$ for some $x_{0} \in \mathbf{X}(\mathbf{A}, \mathbf{b})$,
(b') for each $z \in Z$ such that $\mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \neq \emptyset$ there exists an interval vector $\left[\underline{x}_{z}, \bar{x}_{z}\right]$ satisfying $\mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \subseteq\left[\underline{x}_{z}, \bar{x}_{z}\right]$,
(c') if $z \in Z, \mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \neq \emptyset$, and $\left(\underline{x}_{z}\right)_{j}\left(\bar{x}_{z}\right)_{j} \leq 0$ for some $j$, then $z-2 z_{j} e_{j} \in Z$.
Then $\mathbf{A}$ is regular and

$$
\mathbf{X}(\mathbf{A}, \mathbf{b}) \subseteq \bigcup_{z \in Z_{0}}\left[\underline{x}_{z}, \bar{x}_{z}\right]
$$

holds, where

$$
Z_{0}=\left\{z \in Z \mid \mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \neq \emptyset\right\}
$$

Proof. We shall prove that assumptions ( $\mathrm{a}^{\prime}$ ), ( $\mathrm{b}^{\prime}$ ), ( $\mathrm{c}^{\prime}$ ) imply validity of the assumptions (a), (b), (c) of Theorem 1. (a') and (a) are the same, and (b') clearly implies (b). To prove (c), let $z, y$ be adjacent, $z \in Z, y \in Y_{n}$, and let $\mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \cap \mathbb{R}_{y}^{n} \neq \emptyset$. Then there exists a $j$ such that $z_{k}=y_{k}$ for each $k \neq j$ and $z_{j}=-y_{j}$, and there exists an $x \in \mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \cap \mathbb{R}_{y}^{n}$ which clearly satisfies $x_{j}=0$, hence, by (b'),

$$
\left(\underline{x}_{z}\right)_{j} \leq 0 \leq\left(\bar{x}_{z}\right)_{j}
$$

and therefore

$$
\left(\underline{x}_{z}\right)_{j}\left(\bar{x}_{z}\right)_{j} \leq 0,
$$

hence $y=z-2 z_{j} e_{j} \in Z$ by (c'), which proves (c). Thus the assumptions of Theorem 1 are met and and we obtain that $\mathbf{A}$ is regular and

$$
\mathbf{X}(\mathbf{A}, \mathbf{b}) \subseteq \bigcup_{z \in Z} \mathbb{R}_{z}^{n}
$$

holds, which in conjunction with assumption (b') and the definition of $Z_{0}$ gives

$$
\mathbf{X}(\mathbf{A}, \mathbf{b}) \subseteq \bigcup_{z \in Z}\left(\mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n}\right)=\bigcup_{z \in Z_{0}}\left(\mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n}\right) \subseteq \bigcup_{z \in Z_{0}}\left[\underline{x}_{z}, \bar{x}_{z}\right]
$$

Finally, in the third theorem we specify a way how to enclose the sets $\mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \neq$ $\emptyset, z \in Z$, via solutions of certain nonlinear matrix inequalities. Thus, this theorem describes a construction of a set $Z$ as well as a construction of orthantwise enclosures.

Theorem 3 Let $\mathbf{A}=\left[A_{c}-\Delta, A_{c}+\Delta\right]$ be an $n \times n$ interval matrix, $\mathbf{b}=\left[b_{c}-\delta, b_{c}+\delta\right]$ an interval n-vector, and let $Z$ be a subset of $Y_{n}$ having the following properties:
(a") $\operatorname{sgn}\left(x_{0}\right) \in Z$ for some $x_{0} \in \mathbf{X}(\mathbf{A}, \mathbf{b})$,
(b") for each $z \in Z$ the inequalities

$$
\begin{align*}
\left(Q A_{c}-I\right) T_{z} & \geq|Q| \Delta,  \tag{4.3}\\
\left(Q A_{c}-I\right) T_{-z} & \geq|Q| \Delta \tag{4.4}
\end{align*}
$$

have matrix solutions $Q_{z}$ and $Q_{-z}$, respectively,
(c") if $z \in Z, Q_{-z} b_{c}-\left|Q_{-z}\right| \delta \leq Q_{z} b_{c}+\left|Q_{z}\right| \delta$, and $\left(Q_{-z} b_{c}-\left|Q_{-z}\right| \delta\right)_{j}\left(Q_{z} b_{c}+\left|Q_{z}\right| \delta\right)_{j} \leq 0$ for some $j$, then $z-2 z_{j} e_{j} \in Z$.

Then $\mathbf{A}$ is regular and

$$
\begin{aligned}
\mathbf{X}(\mathbf{A}, \mathbf{b}) & \subseteq \bigcup_{z \in Z_{1}}\left[Q_{-z} b_{c}-\left|Q_{-z}\right| \delta, Q_{z} b_{c}+\left|Q_{z}\right| \delta\right] \\
& \subseteq\left[\min _{z \in Z_{1}}\left(Q_{-z} b_{c}-\left|Q_{-z}\right| \delta\right), \max _{z \in Z_{1}}\left(Q_{z} b_{c}+\left|Q_{z}\right| \delta\right)\right]
\end{aligned}
$$

holds, where

$$
Z_{1}=\left\{z \in Z\left|Q_{-z} b_{c}-\left|Q_{-z}\right| \delta \leq Q_{z} b_{c}+\left|Q_{z}\right| \delta\right\} .\right.
$$

Proof. Let $z \in Z, \mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \neq \emptyset$, and let $Q_{z}$ solve (4.3), so that it satisfies

$$
\begin{equation*}
T_{z} \leq Q_{z} A_{c} T_{z}-\left|Q_{z}\right| \Delta \tag{4.5}
\end{equation*}
$$

Then for each $x \in \mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n}$ we have $T_{z} x=|x|, x=T_{z}|x|$, and

$$
\begin{equation*}
\left|A_{c} x-b_{c}\right| \leq \Delta|x|+\delta \tag{4.6}
\end{equation*}
$$

by the Oettli-Prager theorem ([4], in the current form in [2]). First postmultiplying (4.5) by $|x|$ and later premultiplying (4.6) by $\left|Q_{z}\right|$, we obtain

$$
\begin{aligned}
x & =T_{z}|x| \leq Q_{z} A_{c} T_{z}|x|-\left|Q_{z}\right| \Delta|x| \\
& =Q_{z} A_{c} x-\left|Q_{z}\right| \Delta|x| \\
& =Q_{z}\left(A_{c} x-b_{c}\right)+Q_{z} b_{c}-\left|Q_{z}\right| \Delta|x| \\
& \leq\left|Q_{z}\left(A_{c} x-b_{c}\right)\right|+Q_{z} b_{c}-\left|Q_{z}\right| \Delta|x| \\
& \leq\left|Q_{z}\right|\left|A_{c} x-b_{c}\right|+Q_{z} b_{c}-\left|Q_{z}\right| \Delta|x| \\
& \leq\left|Q_{z}\right|(\Delta|x|+\delta)+Q_{z} b_{c}-\left|Q_{z}\right| \Delta|x| \\
& =Q_{z} b_{c}+\left|Q_{z}\right| \delta .
\end{aligned}
$$

Similarly, since $T_{-z}=-T_{z}$, the inequality (4.4) can be written as

$$
T_{z} \geq-Q_{z} A_{c} T_{z}+\left|Q_{z}\right| \Delta,
$$

and we have

$$
\begin{aligned}
x & =T_{z}|x| \geq Q_{-z} A_{c} T_{z}|x|+\left|Q_{-z}\right| \Delta|x| \\
& =Q_{-z} A_{c} x+\left|Q_{-z}\right| \Delta|x| \\
& =Q_{-z}\left(A_{c} x-b_{c}\right)+Q_{-z} b_{c}+\left|Q_{-z}\right| \Delta|x| \\
& \geq-\left|Q_{-z}\left(A_{c} x-b_{c}\right)\right|+Q_{-z} b_{c}+\left|Q_{-z}\right| \Delta|x| \\
& \geq-\left|Q_{-z}\right|\left|A_{c} x-b_{c}\right|+Q_{-z} b_{c}+\left|Q_{-z}\right| \Delta|x| \\
& \geq-\left|Q_{-z}\right|(\Delta|x|+\delta)+Q_{-z} b_{c}+\left|Q_{-z}\right| \Delta|x| \\
& =Q_{-z} b_{c}-\left|Q_{-z}\right| \delta .
\end{aligned}
$$

In this way we have proved that

$$
\mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \subseteq\left[Q_{-z} b_{c}-\left|Q_{-z}\right| \delta, Q_{z} b_{c}+\left|Q_{z}\right| \delta\right] .
$$

Thus, if we put

$$
\begin{aligned}
& \bar{x}_{z}=Q_{z} b_{c}+\left|Q_{z}\right| \delta, \\
& \underline{x}_{z}=Q_{-z} b_{c}-\left|Q_{-z}\right| \delta,
\end{aligned}
$$

then the assumptions ( $a^{\prime}$ )-( $c^{\prime}$ ) of Theorem 2 are met and the result follows from it since

$$
Z_{0}=\left\{z \in Z \mid \mathbf{X}(\mathbf{A}, \mathbf{b}) \cap \mathbb{R}_{z}^{n} \neq \emptyset\right\} \subseteq\left\{z \in Z \mid \underline{x}_{z} \leq \bar{x}_{z}\right\}=Z_{1} .
$$

## 5 A general method

Theorem 3 has been implemented into a MATLAB-style code in Fig. 5.1. The text is self-explanatory as the same notations are used. The following result is immediate:

Theorem 4 For each $n \times n$ interval matrix $\mathbf{A}$ and for each interval $n$-vector $\mathbf{b}$ the algorithm (Fig. 5.1) in a finite number of steps either computes an enclosure $X$ of the solution set of the interval linear system $\mathbf{A} x=\mathbf{b}$, or fails (produces an empty output).

In an envisaged forthcoming paper, we are going to explain how to solve efficiently the inequalities (4.3), (4.4) and how to reorganize the method so as to compute the optimal enclosure (the interval hull).
(01) function $X=\operatorname{genmeth}(\mathbf{A}, \mathbf{b})$
(02) \% Computes an enclosure $X$ of the solution set
(03) $\%$ of $\mathbf{A} x=\mathbf{b}$, or produces an empty output.
(04) if $A_{c}$ is singular, $X=[]$; return, end
(05) $x_{c}=A_{c}^{-1} b_{c} ; z=\operatorname{sgn}\left(x_{c}\right) ; \underline{x}=x_{c} ; \bar{x}=x_{c}$;
(06) $Z=\{z\} ; D=\emptyset$;
(07) while $Z \neq \emptyset$
(08) select $z \in Z ; Z=Z-\{z\} ; D=D \cup\{z\}$;
(09) find a solution $Q_{z}$ of $\left(Q A_{c}-I\right) T_{z} \geq|Q| \Delta$;
(10) if $Q_{z}$ not found, $X=$ []; return, end
(11) find a solution $Q_{-z}$ of $\left(Q A_{c}-I\right) T_{-z} \geq|Q| \Delta$;
(12) if $Q_{-z}$ not found, $X=[]$; return, end
(13) $\quad \bar{x}_{z}=Q_{z} b_{c}+\left|Q_{z}\right| \delta$;
(14) $\quad \underline{x}_{z}=Q_{-z} b_{c}-\left|Q_{-z}\right| \delta$;
(15) if $\underline{x}_{z} \leq \bar{x}_{z}$
(16) $\quad \underline{x}=\min \left(\underline{x}, \underline{x}_{z}\right) ; \bar{x}=\max \left(\bar{x}, \bar{x}_{z}\right)$;
(17) $\quad$ for $j=1: n$
(18) $\quad z^{\prime}=z ; z_{j}^{\prime}=-z_{j}^{\prime}$;
(19) if $\left(\left(\underline{x}_{z}\right)_{j}\left(\bar{x}_{z}\right)_{j} \leq 0\right.$ and $\left.z^{\prime} \notin Z \cup D\right)$
(20) $Z=Z \cup\left\{z^{\prime}\right\}$;
(21) end
(22) end
(23) end
(24) end
(25) $X=[\underline{x}, \bar{x}]$;

Figure 5.1: A general method for computing enclosures.
